

Questions

Is the information required for using the tool hard to find? In particular, is it possible to estimate the impact of the substitution on the input and output materials after the substitution?

Are the materials types clear or should we provide examples (e.g. for composites)?

Are the units of measure for the different factors practical or we should use different units (e.g. MWh instead of kWh, m³ instead of litres, tonnes instead of kg)?

Are the results clear or we should provide more information? Should the results be displayed as percentages (change of the intensity factors after the substitution)?
